

Statistical Modeling Approaches for CDS Tools Predicting In-Hospital Cardiopulmonary Arrest

Alvin D. Jeffery, PhD, RN
Vanderbilt University School of Nursing

+ Dissertation: Specific Aims

1. Compare the performance of logistic regression, survival analysis, random forests, and random survival forests in the development and validation of a dynamic predictive model for in-hospital cardiopulmonary arrest based on patient characteristics

AJCC AMERICAN JOURNAL OF CRITICAL CARE, September 2018, Volume 27, No. 5

ADVANCING IN-HOSPITAL CLINICAL DETERIORATION PREDICTION MODELS

By Alvin D. Jeffery, PhD, RN, Mary S. Dietrich, PhD, MS, Daniel Fabbri, PhD, Betsy Kennedy, PhD, RN, Laurie L. Novak, PhD, Joseph Coco, MS, and Lorraine C. Mion, PhD, RN

Aim #1: Statistical Model

- Data Source:
 - VU Synthetic Derivative (~170,000 eligible patients, ~0.6% event rate)
- Dependent Variable
 - Cardiopulmonary Arrest (CPT Code 92950) after 1st Hospital Day
- Independent Variables (from 1st Hospital Day)
 - Patient Characteristics (demographics/labs/vital signs)
 - ICD-9 Codes
- Data Analysis
 - Classification vs. Time-to-Event
 - "Traditional" vs. Machine Learning

Table 1
Comparison of analytical approaches to
predicting in-hospital cardiopulmonary arrest^a

Purpose	Approach	
	Statistical	Machine learning
Classification: predicts whether an event will occur	Logistic regression	Random forest
Survival/time to event: predicts how likely an event is at each time point	Cox proportional hazards regression	Random survival forest

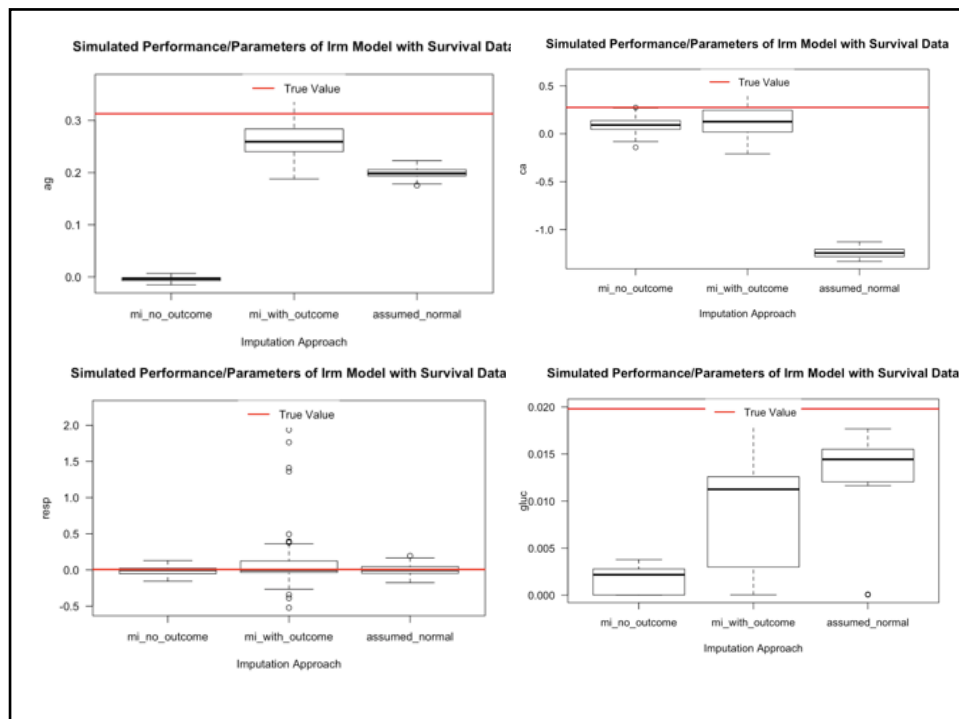

^a Our chosen statistical approaches leverage regression methods. Our chosen machine learning approaches average the results of many decision trees that have been created by splitting a random selection of predictor variables in each tree.

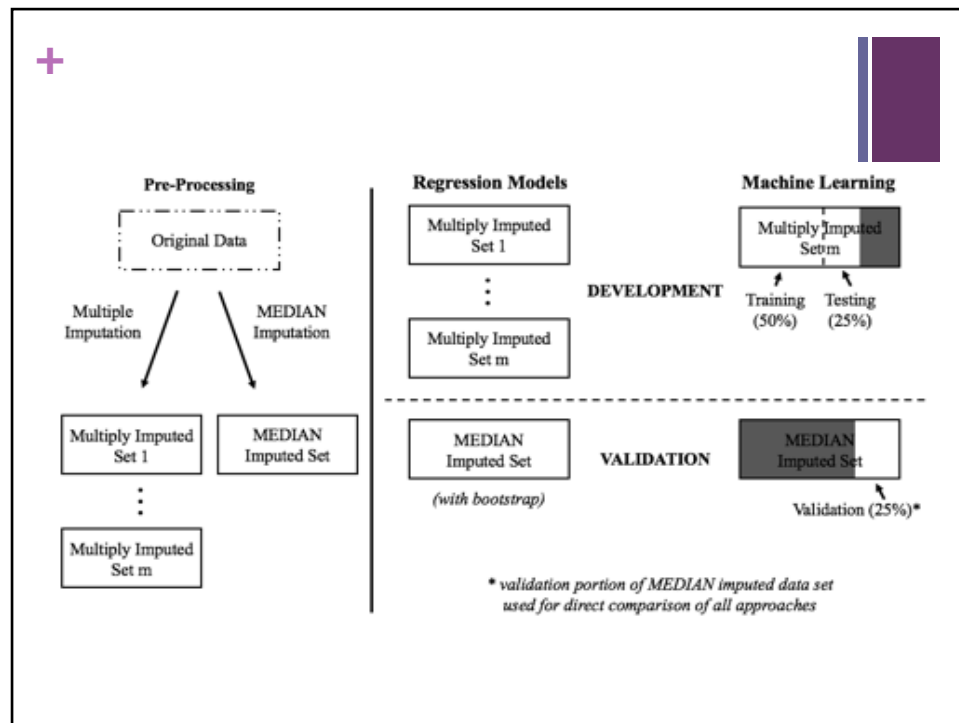

Figure 1. Percentage of missing values for each variable.

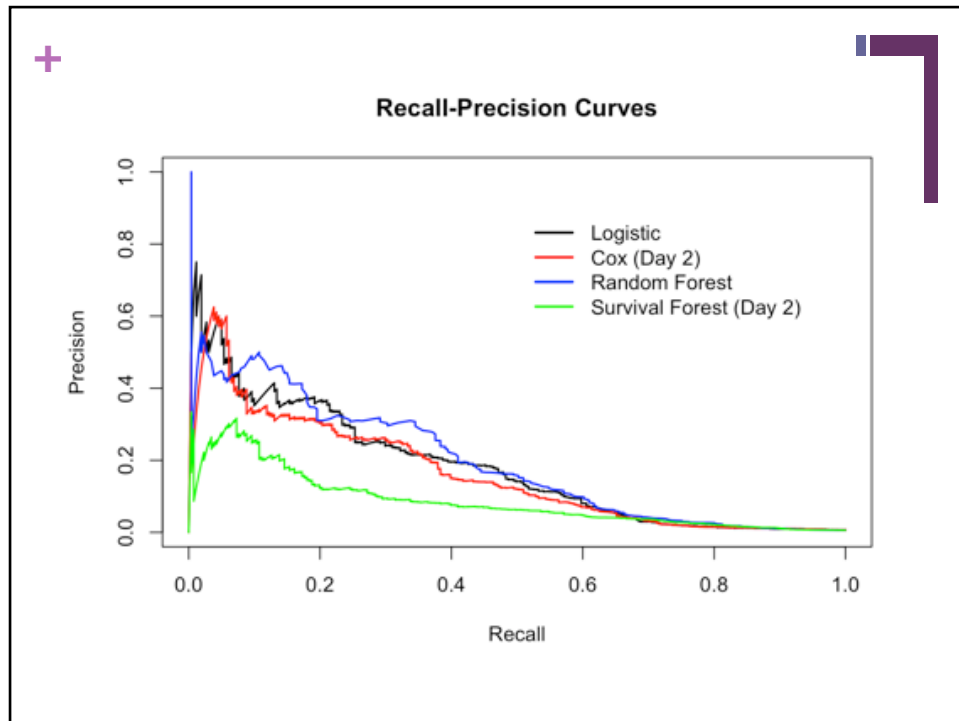

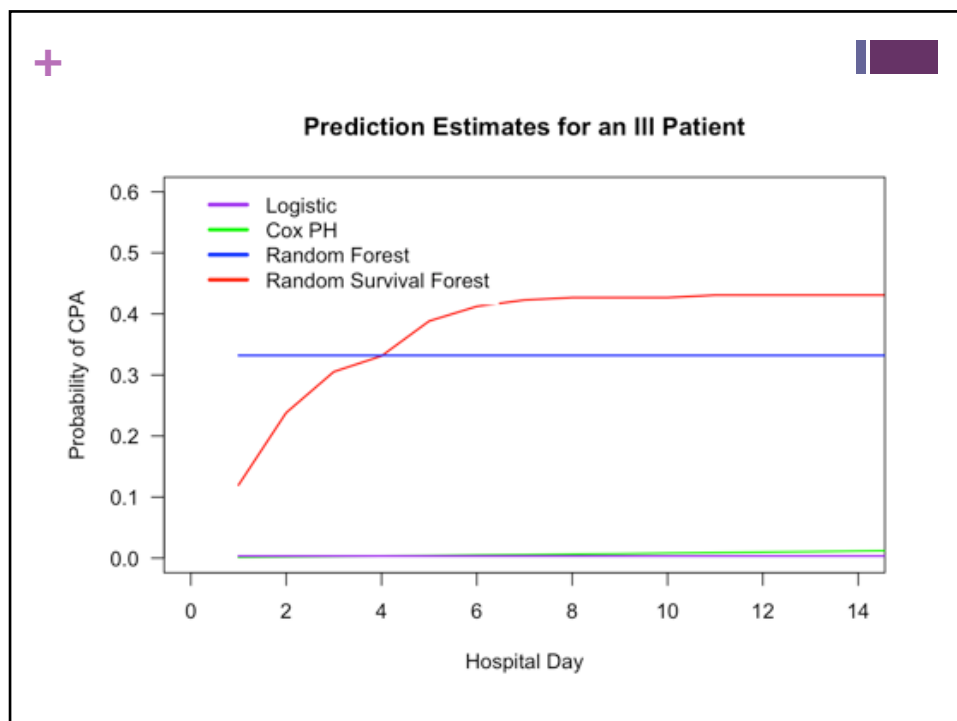

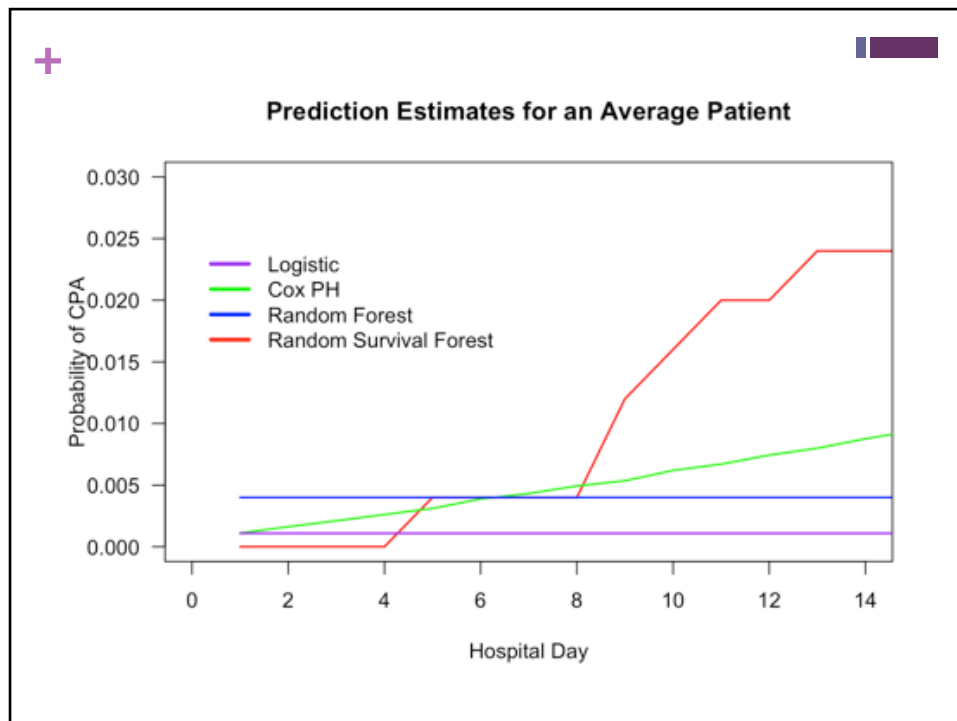

+ Side Track: Simulation

- 10,000,000 patients using 2 approaches:
 - Mimicking variance-covariance matrix of empirical data
 - Mimicking time-to-event distributions & predictors' association with that distribution
- 100 iterations of:
 - Sample 150,000 patients without replacement
 - Induce MCAR & MAR at different proportions
 - Impute with Predicted-Mean-Matching with Chained Equations (similar to Multiple Imputation) +/- Outcome and Missing-Assumed-Normal
 - Build Logistic & Cox PH Models on Imputed Samples
- Compared sample results with "True" population values

+	Variable	Inclusion in Final Models	Reason for Exclusion
	Age	Yes	
	Gender	Yes	
	Race	No	Small sample in some categories resulted in a singular matrix during model fits
	Ethnicity	No	Small sample in some categories resulted in a singular matrix during model fits
	Body Mass Index	Yes	
	Heart Rate	Yes	
	Respiratory Rate	Yes	
	Blood Pressure	No	Data source listed all timestamps at 00:00, so we were unable to determine first value
	Sodium	Yes	
	Potassium	Yes	
	Chloride	No	Could be predicted by other variables in a regression model with $R^2 > 0.9$
	Glucose	Yes	
	Blood Urea Nitrogen	No	Collinear with Creatinine (Spearman's rho ~ 0.4)
	Creatinine	Yes	
	Anion Gap	Yes	
	Calcium	Yes	
	Carbon Dioxide	Yes	
	White Blood Cell Count	Yes	
	Red Blood Cell Count	No	Collinear with Hemoglobin (Spearman's rho ~ 0.8)
	Hemoglobin	Yes	
	Platelet Count	Yes	
	Red Cell Distribution Width	Yes	
	Blood Gas Panel*	No	Missing in > 80% of patients
	Braden Score	No	Missing in > 80% of patients
	ICD-9 Codes	Most	The Obstetrical procedure category was removed because it resulted in a singular matrix during model fits
	CPT Codes	No	Only used for outcome variables
